

# CHRONIC KIDNEY DISEASE

An opportunity to improve how your practice cares for this vulnerable group of patients.

Dr Richard Murray, William Murray

For every 100 patients with chronic kidney disease and moderate to severe kidney function impairment there are:

**7**   
events of acute  
kidney injury per year

**6**   
cardiovascular  
events per year

**7**   
deaths per year

  
**38**  
unplanned hospital  
admissions per year

**2** **ICU**  
admissions to the  
Intensive Care Unit per year

[www.lshtm.ac.uk/ckdaudit](http://www.lshtm.ac.uk/ckdaudit)

## Largest sample of patients with CKD in primary care globally

There was high variability between practices in rates of coding CKD 3-5 (the range lay between 0% and 80% potentially uncoded).

People with CKD which is not recorded (and therefore not known to all those who are caring for that patient) are

- more likely to have **heart attacks and strokes**
- more likely to be **admitted to hospital**
- more likely to develop **acute kidney injury**
- more likely to **die** than those who have been identified in advance.

# Is it safe to prescribe ?

Patient 1- Ramipril 5mgs

GFR 45 and volume depleting acute illness

Patient 2- Metformin

GFR<30

Patient 3- Gabapentin

GFR 40

Patient 4- Canagliflozin 300mgs

GFR 45

# Is it safe to prescribe ? **NOT ALWAYS**

Patient 1- Ramipril 5mgs

GFR 45 and volume depleting acute illness  
**Hold on prescribing**

Patient 2- Metformin

GFR<30 **Stop**

Patient 3- Gabapentin

GFR 40 **Reduce dose by 50%**

Patient 4- Canagliflozin 300mgs

GFR 45 **Reduce to 100mgs**

# Is it safe to prescribe ? High Risk

Patient 1-Ramipril 5mgs

GFR /unknown/ not checked

Patient 2- Metformin

GFR /unknown/ not checked

Patient 3- Gabapentin

GFR/unknown/ not checked

Patient 4- Canagliflozin 300mgs

GFR /unknown/ not checked

Patients who are not coded are twice as likely to have an emergency hospital admission as patients who are coded for CKD

# What did we do

1. We identified all patients with an eGFR <45 (CKD 3b-5) and flagged their files
2. We contacted all patients and arranged a doctor review
3. Review: education verbal and leaflets on lifestyle modification, nephrotoxic OTC drugs, checked urine for blood and sent for albumin/creatinine ratio (independent cardiovasc. risk factor).
4. Coding
5. We significantly changed our software so that the opening screen of each patient's file identified the patient as having chronic kidney disease with their CKD code, most recent blood pressure recording, lipid profile, BMI, haemoglobin, smoking status and chronic medication prescribed.

Product name	Dosage
Lipitor 20 mg tablets	1 tabs daily
aspirin 75 mg	1 tabs daily
rampiril 5 mg	1 tabs daily

# Summary

- Is it important ? Yes (For every 100 patients with moderate to severe CKD there are 7 deaths, 38 unplanned admissions, 7 acute kidney and 6 cardiovascular events per year).
- Can a General Practitioner make a difference ? Yes (Following changes : 62% increase in patients coded, 100% increase in all relevant data recorded in one screen, 45% increase in patients aware of their diagnosis, 100% of patients now educated on OTC medications to avoid and how to manage acute illnesses).
- Can we rely on secondary care to do this ? No (majority of CKD patients managed solely in the community)

# Thank you for listening

## Any Questions?

“where CKD is recognised in this population, patients are often nihilistically treated”

- “there is building high-level evidence that the presence of CKD is a greater risk factor for cardiovascular disease than is diabetes”
